Summary
Database Systems - General Security Requirements

Table of Contents

1. Introduction

This security document has been prepared based on the general security policies of the group.
The security requirement is used as a basis for an approval in the PSA process, among other things. It also serves as an implementation standard for units which do not participate in the PSA process. These requirements shall be taken into account from the very beginning, including during the planning and decision-making processes.
When implementing these security requirements, the precedence of national, international and supranational law shall be observed.

2. Hardening

This chapter lists the requirements for hardening database systems. The measures are comparable to those for hardening the operating system. They reduce the likelihood of successful attacks on database systems and/or the consequences thereof.

Req 1	The software used must be obtained from trusted sources and checked for integrity.

The software used on the system must be obtained from trusted sources and checked for integrity before installation.

This requirement applies to all types of software:

- Firmware and microcode for hardware components
- Operating systems
- Software Libraries
- Application Software
- Pre-integrated application solutions, such as software appliances or containers

as well as other software that may be used.

Trusted Sources

Trusted sources are generally considered to be:

- the official distribution and supply channels of the supplier
- third party distributors, provided they are authorized by the supplier and are a legitimate part of the supplier´s delivery channels
- internet downloads, if they are made from official provisioning servers of the supplier or authorized distributors
  (1) If the provisioning server offers various forms of downloads, those protected by encryption or cryptographic signatures must be preferred to those without such protection.
  (2) If the provisioning server secures the transport layer using cryptographic protocols (e.g. https, sftp), the associated server certificates or server keys/fingerprints must be validated with each download to confirm the identity of the provisioning server; if validation fails, the download must be cancelled and the provisioning server has to be considered an untrusted source.

Integrity Check

The integrity check is intended to ensure that the received software is free of manipulation and malware infection. If available, the mechanisms implemented by the supplier must be used for checking.
Valid mechanisms are:

- physical seals or permanently applied certificates of authenticity (if the software is provided on physical media)
- comparison of cryptographic hash values (e.g. SHA256, SHA512) of the received software against target values, which the supplier provides separately
- verification of cryptographic signatures (e.g. GPG, certificates) with which the supplier provides its software

In addition, a check of the software using an anti-virus or anti-malware scanner is recommended (if the vendor has not implemented any of the aforementioned integrity protection mechanisms for its software, this verification is mandatory).

Extended integrity checking when pulling software from public registries

Public registries allow developers to make any of their own software projects available for use. The range includes projects from well-known companies with controlled development processes, as well as from smaller providers or amateur developers.
Examples of such registries are:

- Code registries (e.g. GitHub, Bitbucket, SourceForge, Python Package Index)

- Container registries (e.g. Docker Hub)

Software from public registries must undergo an extended integrity check before deployment.
In addition to the integrity check components described in the previous section, the extended check is intended to explicitly ensure that the software actually performs its function as described, does not contain inherent security risks such as intentionally implemented malware features, and is not affected by known security vulnerabilities. If the software has direct dependencies on third-party software projects (dependencies are very typical in open source software), which must also be obtained and installed for the use of the software, these must be included in the extended integrity check.

Suitable methods for an extended integrity check can be, for example:

- Strict validation of project/package names (avoidance of confusion with deliberately imitated malicious software projects)
- dynamic code analysis / structured functional checks in a test environment
- static code analysis using a linter (e.g. Splint, JSLint, pylint)
- Examination using a security vulnerability scanner (e.g. Qualys, Nessus)
- Examination using a container security scanner (e.g. JFrog Xray, Harbor, Clair, Docker Scan)
- Examination using an SCA (Software Composition Analysis) tool or dependency scanner (e.g. OWASP Dependency Check, Snyk)

The test methods must be selected and appropriately combined according to the exact form of software delivery (source code, binaries/artifacts, containers).

Motivation: Software supply chains contain various attack vectors. An attacker can start at various points to manipulate software or introduce his own routines and damage or control the target environment in which the software is subsequently used. The attack can occur on the transport or transmission path or on the provisioning source itself. Accordingly, an attack is facilitated if software is not obtained from official and controlled sources or if an integrity check is omitted.
There is a particular risk for software obtained from public registries, as these are open to anyone for the provision of software projects. Perfidious attack methods are known, in which the attacker first provides completely inconspicuous, functional software for a while and as soon as it has established itself and found a certain spread, deliberately hidden malicious code is integrated in future versions. Other methods rely on similar-sounding project names for widely used existing projects or overruling version numbers to inject manipulated software into any solutions based on them.

Implementation example: Obtain the software via the official delivery channels of the supplier. Upon receipt of the software, immediately check for integrity using cryptographic checksums, as provided by the supplier, as well as scan for any infections by known malware using anti-malware / anti-virus scanners. Storage of the tested software on an internal, protected file storage and further use (e.g. rollout to the target systems) only from there.

For this requirement the following threats are relevant:
- Unauthorized modification of data
- Unnoticeable feasible attacks
- Attacks motivated and facilitated by information disclosure or visible security weaknesses

For this requirement the following warranty objectives are relevant:

ID: 3.01-2/7.0

Req 2	Only required software may be used on the system.

In the installation routines for software provided by the supplier, individual components of the software are often preselected as standard installations, which are not necessary for the operation and function of a specific system. This also includes parts of software that are installed as application examples (e.g. default web pages, sample databases, test data), but are typically not used afterwards.

Such components must be specifically deselected (not installed) during the installation of the system or - if deselection during installation is not possible - removed immediately afterwards.

In principle, no software may be used that is not required for the operation, maintenance or function of the system.

Motivation: Vulnerabilities in a system's software are gateways for attackers. By uninstalling unnecessary components, the potential attack surfaces can be significantly reduced.

For this requirement the following threats are relevant:
- Unauthorized use of services or resources
- Attacks motivated and facilitated by information disclosure or visible security weaknesses

For this requirement the following warranty objectives are relevant:

ID: 3.01-3/7.0

Req 3 Features that are not required in the software and hardware used must be deactivated.

During the initial installation of software, features may have been activated by default that are not necessary for the operation and functionality of the specific system. Features are usually an integral part of the software that cannot be deleted or uninstalled individually.

Such features must be disabled immediately after the initial installation through the software's configuration settings, so that they remain permanently disabled even after the system is rebooted.

Even before delivery or during initial commissioning, features may have been activated by default in the hardware that are not required for the purpose of the specific system. Such functions, for example unnecessary interfaces, must also be permanently deactivated immediately after initial commissioning.

Motivation: A system's hardware or software often contains enabled features that are not being used. Such features can be an unnecessary target for manipulation. Furthermore, there is a potential that unauthorized access to areas or data of the system can be created.

Implementation example: [Example 1]
Deactivation of debugging functions in the software that are used in the event of fault analysis, but do not have to be active during normal operation.

[Example 2]
Disabling unused network interfaces of a server.

For this requirement the following threats are relevant:
- Unauthorized use of services or resources
- Attacks motivated and facilitated by information disclosure or visible security weaknesses

For this requirement the following warranty objectives are relevant:

ID: 3.01-4/7.0

Req 4 Unnecessary services must be disabled.

After the installation of systems and software products, supplier-preset, local or network-accessible services are often active that are not required for the operation and functionality of the specific system in the intended operating environment.

However, in principle only the services actually required may be active on a system.

Accordingly, all services that are not required on a system must be completely disabled immediately after installation. It must be ensured that these services remain disabled even after the system is restarted.

Motivation: Active services that are not required unnecessarily increase the attack surface of a system and, as a direct *consequence, the risk of a successful compromise. This risk can be further increased if - as is often observed with services that are not required - a targeted examination and optimization of the configuration with regard to security does not take place sufficiently.*

For this requirement the following threats are relevant:
- Unauthorized use of services or resources
- Attacks motivated and facilitated by information disclosure or visible security weaknesses

For this requirement the following warranty objectives are relevant:

ID: 3.01-5/7.0

Req 5	The accessibility of activated services must be restricted.

In principle, a service provided must be completely deactivated on all interfaces of the system through which accessibility of the service is not required for the proper operation of the system. The deactivation is primarily to be implemented by a corresponding configuration of the service or operating system. In cases where the available configuration options do not allow deactivation on individual interfaces, a local filter ("Host Firewall") may instead be used on the system to block access to the service via unnecessary interfaces.

The accessibility of a service via the required interfaces must also be restricted to legitimate communication partners. The restriction must be implemented by a corresponding configuration of the service or operating system or by means of a local filter ("Host Firewall"). Alternatively, this task may be outsourced to a network-side filter element, provided that the system is located in a suitable separate network segment and communication with this segment is only possible via the network-side filter element.

Motivation: By deactivating services on interfaces through which accessibility is not necessary, as well as by restricting possible communication partners, the attack surface offered by a system can be greatly reduced.

Implementation example: An SNMP service used to monitor a system is enabled exclusively on the dedicated management network interface of the system. A firewall also regulates that only the legitimate monitoring system of the infrastructure environment can reach this service.

For this requirement the following threats are relevant:
- Unauthorized use of services or resources
- Attacks motivated and facilitated by information disclosure or visible security weaknesses

For this requirement the following warranty objectives are relevant:

ID: 3.01-6/7.0

Req 6	Known vulnerabilities in the software or hardware of the system must be fixed or protected against misuse.

Known vulnerabilities in software and hardware components must be fixed by installing available system updates from the supplier (e.g. patches, updates/upgrades). Alternatively, the use of workarounds (acute solutions that do not fix the vulnerability, but effectively prevent exploitation) is permissible. Workarounds should only be used temporarily and should be replaced by a regular system update as soon as possible in order to completely close the vulnerabilities.

Components that contain known, unrecoverable vulnerabilities must not be used in a system.

The treatment of newly discovered vulnerabilities must also be continuously ensured for the entire deployment phase of the system and implemented in the continuous operating processes of security patch management.

Motivation: The use of components without fixing contained vulnerabilities significantly increases the risk of a successful compromise. The attacker is additionally favored by the fact that, as a rule, not only detailed information on vulnerabilities that have already become known is openly available, but often also already adapted attack tools that facilitate active exploitation.

Implementation example: Following the initial installation of an operating system from an official installation medium, all currently available patches and security updates are installed.

Additional information:
The primary sources of known vulnerabilities in software/hardware are lists in the release notes as well as the security advisories from the official reporting channels of the supplier or independent CERTs. In particular, the reporting channels are sensibly integrated into continuous processes of security patch management for a system, so that newly discovered vulnerabilities can be registered promptly and led into operational remedial measures.
As a complementary measure to the detection of potentially still contained types of vulnerabilities that have in principle already become known, targeted vulnerability investigations of the system can be carried out. Particularly specialized tools such as automated vulnerability scanners are suitable for this purpose. Examples include: Tenable Nessus, Qualys Scanner Appliance.

For this requirement the following threats are relevant:
- Unauthorized access to the system
- Unauthorized access or tapping of data
- Unauthorized modification of data
- Unauthorized use of services or resources
- Disruption of availability
- Denial of executed activities
- Unnoticeable feasible attacks
- Attacks motivated and facilitated by information disclosure or visible security weaknesses

For this requirement the following warranty objectives are relevant:

ID: 3.01-10/7.0

2.1. Default databases

Req 7	(Default) databases that are not required must be deleted on the database system.

Motivation: When installing database systems, test or practice databases are often installed which are not required once the database goes productive. In the past, vulnerabilities of these test databases have become known which allow an attacker to gain privileged rights on the database system. Such knowledge enables an attacker to access the database system. Therefore, all databases that are not required shall be deleted.

For this requirement the following threats are relevant:
- Unauthorized use of services or resources

For this requirement the following warranty objectives are relevant:

ID: 3.16-7/6.0

2.2. Users and roles

Req 8	(Default) users and (default) roles that are not required must be deleted.

Motivation: When installing a database system, a large number of users and roles are automatically installed, which are not required to operate the database. These are envisaged, for instance, for practice and test databases. Knowledge of default users and roles allows an attacker to gain (privileged) access to the database system. Therefore, users and roles that are not needed for database functions shall be deleted.

For this requirement the following threats are relevant:
- Unauthorized access to the system

For this requirement the following warranty objectives are relevant:

ID: 3.16-8/6.0

2.3. Service minimization

Req 9	Only those database instances which -have the same protection requirements (data protection class), -are under a single customer administrative authority and; -are operated, in terms of administration, by the same group of people,may be operated on one operating system instance (with physical or virtualized hardware).

Motivation: If server hardware is used multiple times by multiple database systems, the risk increases of a larger group of people obtaining unauthorized access to systems for which they are not responsible technically or in terms of administration.

Implementation example: If server hardware is used multiple times by multiple database systems, the risk increases of a largergroup of people obtaining unauthorized access to systems for which they are not responsible technically or interms of administration.

For this requirement the following threats are relevant:

- Unauthorized access to the system
- Unauthorized access or tapping of data
- Unauthorized use of services or resources
- Unnoticeable feasible attacks

For this requirement the following warranty objectives are relevant:

ID: 3.16-9/6.0

2.4. Passwords

Req 10	If passwords are used as an authentication attribute, those must be stored using a suitable and approved "Password Hashing" method to protect against offline-attacks like brute force or dictionary attacks.

This requirement relates to the storage of passwords in all types of user databases, as used in this system, in order to authenticate incoming access (local or remote) by users or other systems.

If an attacker obtains the copy of a user database of the system, he is able to bring it into a fully independent environment and utilize automatized dictionary or brute force attacks to determine contained passwords. Specialized tools in combination with high computing power allow for high cracking rates in a relatively short period of time, if protective measures are insufficient. Due to the independency from the source system, such an offline attack happens unnoticed.

The following countermeasure must be implemented, since this ensures best possible protection against offline attacks:

- passwords must be stored using a cryptographic one-way function ("Password Hashing") which is suitable for that purpose and verifiably secure as matters stand

Please Note:
valid password hashing algorithms are described in Security Requirement Catalog "3.50 Cryptographic Algorithms and Security Protocols".

Explicitly NOT PERMISSIBLE is:

- to store passwords in cleartext

- to store passwords in any format which can be directly backcalculated
- to store passwords using reversible encryption

Please Note:
In this context, "directly backcalculatable formats" refers to those that simply encode the password, without involving a secret key in the transformation process. Since the password will no longer show up as original cleartext after it has been processed, those formats may easily be mistaken to provide confidentiality. Effectively, they do not offer any protection. The enconding is fixed and therefore an attacker can easily make use of it to compute the original cleartext password from the encoded string.
Examples for directly backcalculatable formats are: "base64", "rot13"
"Reversible" are all encryption methods which, using the appropriate key, enable encrypted content to be transformed back into the original content. Accordingly, with reversible encryption there is always the challenge of keeping the key secure and protecting it from unauthorized access. Reversibility is a required fundamental property in many areas of encryption applications, e.g. for transferring confidential messages, but it is counterproductive for storing passwords: a stored password must remain comparable by means of technical methods, but it must no longer be possible to convert it back into plain text in order to protect it as well as possible from unauthorized viewing.
Examples for reversible encryption are: "AES", "CHACHA20", "3DES", "RSA"

Motivation: Without protective measures, an attacker in possession of a user database copy is able to determine masses of contained passwords in short time by merely trying out character string combinations or making use of dictionaries. Passwords stored in cleartext or any backcalculatable format are fully defenseless to an offline attack. Once a password has been ascertained it can be used by an attacker for unauthorized access to the system and the data on it.

For this requirement the following threats are relevant:
- Unauthorized access to the system
- Unauthorized access or tapping of data
- Unauthorized modification of data
- Unauthorized use of services or resources
- Denial of executed activities
- Attacks motivated and facilitated by information disclosure or visible security weaknesses

For this requirement the following warranty objectives are relevant:

ID: 3.01-24/7.0

Req 11	If a password is used as an authentication attribute, it must have at least 12 characters and contain three of the following categories: lower-case letters, upper-case letters, digits and special characters.

A system may only accept passwords that comply with the following complexity rules:
- Minimum length of 12 characters.
- Comprising at least three of the following four character categories:
  - lower-case letters
  - upper-case letters
  - digits
  - special characters

The usable maximum length of passwords shall not be limited to less then 25 characters. This will provide more freedom to End Users when composing individual memorizable passwords and helps to prevent undesired behavior in password handling.

When a password is assigned, the system must ensure that the password meets these policies. This must be preferably enforced by technical measures; if such cannot be implemented, organizational measures must be established.
If a central system is used for user authentication [see also Root Security Requirements Document[i] "3.69 IAM (Identity Access Management) - Framework"], it is valid to forward or delegate this task to that central system.

Permissible deviation in the password minimum length
Under suitable security-related criteria, conditions can potentially be identified for a system that enable the minimum password length to be reduced:

- It is generally permissible to reduce the minimum password length for systems that use additional independent authentication attributes within the authentication process in addition to the password (implementation of 2-Factor or Multi-Factor Authentication).
- Any reduction in the minimum password length must be assessed individually by a suitable technical security advisor (e. g. a PSM from Telekom Security) and confirmed as permissible. In the assessment, the surrounding technical, organizational and legal framework parameters must be taken into account, as well as the system-specific protection requirements and the potential amount of damage in the event of security incidents.
- The absolute minimum value of 8 characters length for passwords must not be undercut.

Motivation: Passwords with the above complexity offer contemporary robustness against attacks coupled with acceptable user friendliness. Passwords with this level of complexity have proven their efficiency in practice. Trivial and short passwords are susceptible to brute force and dictionary attacks and are therefore easy for attackers to determine. Once a password has been ascertained it can be used by an attacker for unauthorized access to the system and the data on it.

For this requirement the following threats are relevant:
- Unauthorized access to the system
- Unauthorized access or tapping of data
- Unauthorized modification of data
- Unauthorized use of services or resources
- Denial of executed activities

For this requirement the following warranty objectives are relevant:

ID: 3.01-26/7.0

Req 12	If a password is used as an authentication attribute for technical accounts, it must have at least 30 characters and contain three of the following categories: lower-case letters, upper-case letters, digits and special characters.

Technical user accounts are characterized by the fact that they are not used by people. Instead, they are used to authenticate and authorize systems to each other or applications on a system.

A system must only use passwords for technical user accounts that meet the following complexity:

- Minimum length of 30 characters
- Comprising at least three of the following four character categories:
  - lower-case letters
  - upper-case letters
  - digits
  - special characters

Motivation: Due to their use in machine-to-machine (M2M) communication scenarios, technical user accounts are often equipped with privileges that can be of high interest to an attacker to compromise infrastructures. Without mechanisms of extensive compromise detection, the risk of a password being determined or broken by an attacker can increase significantly over time. A significant increase in password length counteracts these risks and can also be implemented particularly easily in M2M scenarios, since handling a very long password is not a particular challenge for a machine (as opposed to a person).

For this requirement the following threats are relevant:
- Unauthorized access to the system
- Unauthorized access or tapping of data
- Unauthorized modification of data
- Unauthorized use of services or resources
- Denial of executed activities

For this requirement the following warranty objectives are relevant:

ID: 3.01-27/7.0

Req 13	If a password is used as an authentication attribute, the reuse of previous passwords must be prevented.

A history of the previously used passwords must be recorded for each user account. When a password change is initiated for a user account, the new password must be compared with this password history. If the reuse of a password is detected, the password change must be rejected. This validation process must be implemented in the system on the basis of technical measures. If a central IAM system is used for user authentication, the implementation can be forwarded to the central IAM system or outsourced there [see also Root Security Requirements Document[i] "3.69 IAM (Identity Access Management) - Framework"].

In general, the password history should ensure that a password that has already been used can never be used again.

However, due to technical limitations, a password history cannot be recorded indefinitely in many IT/NT products. In this case, the following basic rules must be observed:

- a password that has already been used must not be reusable for a period of at least 60 days (measured from the point in time at which the affected password was replaced by another)
- in systems in which the period of at least 60 days cannot be implemented, the longest possible period must be configured. In addition, it must be confirmed by a Project Security Manager (PSM) that the configured period is still sufficient in the overall context of the system with regard to the security requirement.

Annotation:
Some IT/NT products do not offer any technical configuration parameters with which the password history can be linked directly to a time period, but only allow the definition of the number of passwords to be recorded. In such cases, the time period can alternatively be ensured by linking the following, usually generally available configuration parameters. Within the resulting policy, a user can only change his password once a day and, due to the number of passwords recorded, can reuse an old password effectively after 60 days at the earliest.

- Minimum Password Age: 1 day
- Password History: Record of the last 60 passwords used

With this implementation variant, it should be noted that the minimum age for the password should not be more than one day in order not to inappropriately restrict the user with regard to the fundamental need to be able to change the password independently at any time.

Motivation: Users prefer passwords that are easy to remember and often use them repeatedly over long periods of time when the system allows. From the user's point of view, the behavior is understandable, but effectively leads to a considerable reduction in the protective effect of this authentication parameter. With adequate knowledge of the user or information obtained from previous system compromises, an attacker can gain access to supposedly protected user accounts. Particularly in situations in which new initial passwords are assigned centrally as part of an acute risk treatment, but users change them immediately to a previous password for the sake of simplicity, there is a high risk that an attacker will resume illegal access. It is therefore important to prevent users from reusing old passwords.

Implementation example: [Example 1]
Linux System

set entry in /etc/login.defs

```
PASS_MIN_DAYS 1
```

and additionaly set entries in PAM Konfiguration

```
password requisite pam_pwquality.so try_first_pass local_users_only enforce-for-root retry=3 remember=60
password sufficient pam_unix.so sha512 shadow try_first_pass use_authtok remember=60
```

[Example 2]
Windows System

set entries in GPO

Computer Configuration\Policies\Windows Settings\Security Settings\Account Policies\Password Policy\Minimum password age = **1**
Computer Configuration\Policies\Windows Settings\Security Settings\Account Policies\Password Policy\Enforce password history = **24** (technical maximum)

For this requirement the following threats are relevant:

- Unauthorized access to the system
- Unauthorized access or tapping of data
- Unauthorized modification of data
- Unauthorized use of services or resources
- Denial of executed activities
- Attacks motivated and facilitated by information disclosure or visible security weaknesses

For this requirement the following warranty objectives are relevant:

ID: 3.01-28/7.0

Req 14	If a password is used as an authentication attribute, it must be changed after 12 months at the latest.

The maximum permitted usage period for passwords is 12 months.
If a password reaches the maximum permitted usage period, it must be changed.

For this purpose, the system must automatically inform the user about the expired usage period the next time he logs on to the system and immediately guide him through a dialog to change the password. Access to the system must no longer be permitted without a successfully completed password change.
For technical user accounts (M2M or Machine-2-Machine), which are used for the authentication and authorization of systems among themselves or by applications on a system, automated solutions must also be implemented to comply with the permitted usage period for passwords.

Alternatively, if such an automatic mapping of the process for changing the password cannot be implemented, an effective organizational measure must be applied instead, wich ensures a binding manual password change at the end of the permissible period of use.

Motivation: Unlike more modern authentication attributes, passwords are easier to attack. Without specific measures for reliable, technically automated detection of compromises, the risk of a password being discovered or broken by an attacker can increase considerably over time.

For this requirement the following threats are relevant:

- Unauthorized access to the system
- Unauthorized access or tapping of data
- Unauthorized modification of data
- Unauthorized use of services or resources
- Attacks motivated and facilitated by information disclosure or visible security weaknesses

For this requirement the following warranty objectives are relevant:

ID: 3.01-30/7.0

Req 15	If passwords are used as an authentication attribute, they must not be displayed in plain text during input.

Passwords must not be displayed in legible plain text on screens or other output devices while they are entered. A display while entering must not allow any conclusions to be drawn about the characters actually used in the password.

This requirement applies to all types of password input masks and fields.
Examples of this are dialogs for password assignment, password-based login to systems or changing existing passwords.

Exceptions:

- Within an input field, an optional plain text representation of a password is permitted, provided that this plaintext representation serves a valid purpose, exists only temporarily, has to be explicitly activated by the legitimate user on a case-by-case basis and can also be deactivated again immediately by the latter.
  A valid purpose would be, for example, to allow the legitimate user an uncomplicated visual check, if necessary, that he has entered the password correctly in a login dialog before finally completing the login.
  Such an optional plain text representation of a password must remain fully in the control of the legitimate user so that he can decide on its activation/deactivation according to the situation. In the default setting of the system, the plain text representation must be deactivated.
- The typical behavior on many mobile devices (smartphones) of displaying each individual character very briefly in plain text when entering a password - in order to make it easier for the user to control input - is fundamentally permissible there. However, the full password must never be displayed in plain text on the screen.

Motivation: In the case of a plain text display, there is a risk that third parties can randomly or deliberately spy on a password via the screen output while typing.

Implementation example: When displayed on the screen, each individual character is uniformly replaced by a "*" while entering a password.

For this requirement the following threats are relevant:
- Unauthorized access to the system
- Unauthorized access or tapping of data
- Unauthorized modification of data
- Unauthorized use of services or resources
- Denial of executed activities
- Attacks motivated and facilitated by information disclosure or visible security weaknesses

For this requirement the following warranty objectives are relevant:

ID: 3.01-31/7.0

Req 16	(Default) passwords on database systems muss be changed.

Motivation: Many database manufacturers provide various users with (default) passwords (sa/blank; DBSNMP/DBSNMP, etc.) during installation. An attacker can exploit the existence of these (default) passwords to obtain what tends to be privileged access to the database system.

For this requirement the following threats are relevant:
- Unauthorized access to the system

For this requirement the following warranty objectives are relevant:

ID: 3.16-16/6.0

2.5. Principle of least privilege

Req 17	All database services muss be set up in accordance with the least privilege principle on operating-system level.

Motivation: By using the least privilege principle, the risk of system corruption can be reduced.

For this requirement the following threats are relevant:
- Unauthorized access to the system
- Unauthorized access or tapping of data
- Unauthorized modification of data
- Unauthorized use of services or resources

For this requirement the following warranty objectives are relevant:

ID: 3.16-17/6.0

Req 18	A database service muss not run with root or administrative rights.

Motivation: If a database server runs with highly privileged operating-system rights (root, administrator), an attacker can completely take over a database system by exploiting a vulnerability (access to the file system or execution of files).

For this requirement the following threats are relevant:
- Unauthorized access to the system
- Unauthorized access or tapping of data
- Unauthorized modification of data
- Unauthorized use of services or resources

For this requirement the following warranty objectives are relevant:

ID: 3.16-18/6.0

2.6. SQL functions and packages

This section defines requirements for extensions of the standard SQL command language through additional program packages. These program packages enable often access to operating system/file level or to external network services (e.g. HTTP servers).

Req 19	Extended SQL functions that are not required (e.g. T-SQL, PL/SQL, SQL PL, extended stored procedures) and/or packages from the database system muss be deleted.

Motivation: In many instances an attacker exploits such functions to transfer malware onto the system or execute commands with privileged rights.

For this requirement the following threats are relevant:
- Unauthorized use of services or resources

For this requirement the following warranty objectives are relevant:

ID: 3.16-19/6.0

2.7. SQL extensions with operating-system or network access

Req 20	Database functions which permit access to operating-system files must be deleted or deactivated.

Motivation: Some database systems allow access to the operating-system level via special stored procedures or SQL functions. A multitude of vulnerabilities of these procedures are known which allow an attacker to gain unauthorized access to a system or execute malware on the target system. These procedures are often provided with unnecessarily high, mainly privileged rights or allow anyone to execute programs without authentication.
For example, malware exploits the procedures MS-SQL: xp_cmdshell and Oracle: utl_tcp.

For this requirement the following threats are relevant:
- Unauthorized use of services or resources

For this requirement the following warranty objectives are relevant:

ID: 3.16-20/6.0

Req 21	Database functions which allow access to other network services (e.g. ,SMTP, HTTP, SNMP, FTP etc.), must be deleted or deactivated.

Motivation: Some database systems provide functions that are normally offered by an application server. For instance it is possible via special stored procedures to send e-mails or launch web queries to external systems.

For this requirement the following threats are relevant:
- Unauthorized use of services or resources

For this requirement the following warranty objectives are relevant:

ID: 3.16-21/6.0

Req 22	Database functions which allow access to the operating system level or network services, must not be accessible by the roles / groups "Public" and / or "Everyone".

Motivation: Withdrawing rights can prevent the use of database functions to gain unauthorized access to network services and the operating-system level. Functions to execute operating-system commands and to use network services are thus only available to authorized users, and not to everyone.

For this requirement the following threats are relevant:
- Unauthorized access to the system
- Unauthorized access or tapping of data
- Unauthorized modification of data
- Unauthorized use of services or resources

For this requirement the following warranty objectives are relevant:

ID: 3.16-22/6.0

2.8. Access rights

Req 23	The operating-system rights for the database files and directories (program, control, trace and log files) must be assigned exclusively to the database system’ s operating-system account.

Some database systems store sensitive account data in plain text in trace or log files. Therefore, access rights to sensitive files and directories on the database system MUST be set so that non-administrative users do not have any read, write or execution rights.

Access to essential system files and directories on the database system must be reserved for the database system's user account.

Motivation: By implementing restrictive access rights, the risk of manipulation can be substantially reduced.

For this requirement the following threats are relevant:
- Unauthorized access to the system
- Unauthorized access or tapping of data
- Unauthorized modification of data
- Unauthorized use of services or resources

For this requirement the following warranty objectives are relevant:

ID: 3.16-23/6.0

3. Data communications

This chapter summarizes security requirements that relate to querying and sharing data from other database systems.

The querying or sharing of data can be implemented either by means of so-called ad-hoc queries, or by setting a data connection to share data between the systems. The terminology and the technical implementation of such a data connection varies greatly among manufacturers (MS-SQL: linked servers/replication; Oracle: database links; DB2: connections). To simplify matters, the term 'database connections' is used below in a general sense.

Req 24	Database accesses between various database systems must be comply with the least privilege principle.

-

Motivation: Limiting the access rights reduces the attack surface.

For this requirement the following threats are relevant:
- Unauthorized access to the system
- Unauthorized access or tapping of data
- Unauthorized modification of data
- Unauthorized use of services or resources

For this requirement the following warranty objectives are relevant:

ID: 3.16-24/6.0

Req 25	Database accesses between various database systems must be made via an individual user account.

Motivation: Accesses shall be made via a special user. Only in this way can access rights be individually restricted to the absolute minimum level.

For this requirement the following threats are relevant:
- Unauthorized access to the system
- Unauthorized access or tapping of data
- Unauthorized modification of data
- Unauthorized use of services or resources

For this requirement the following warranty objectives are relevant:

ID: 3.16-25/6.0

4. System monitoring

4.1. Logging

Req 26	Accesses to database systems, as well as critical database procedures and database content must be logged.

Secure, traceable database operation requires important operating information to be logged. This includes, for instance, the logging of failed login attempts to uncover possible intrusion attempts.
Logging of security-relevant user actions shall comply with national legislation currently in force.
When implementing measures resulting from this Requirement, the applicable participation rights of the responsible employee representatives/trade unions as well as the works and collective agreements shall be observed.

For this requirement the following threats are relevant:
- Unnoticeable feasible attacks

For this requirement the following warranty objectives are relevant:

ID: 3.16-26/6.0

Req 27	Security relevant events must be logged with a precise timestamp and a unique system reference.

Systems must log the occurrence of security-relevant incidents. So that these events can be evaluated and classified, they must be logged together with a unique system reference (e.g., host name, IP or MAC address) and the exact time the incident occurred ("Timestamp").

Exceptions of this requirement are systems for which logging cannot be implemented because of building techniques, use case or operation area. Examples for these kind of systems are customer devices such as Smartphones or IADs/home gateways (e.g. Speedport).

The Timestamp of a logged event must contain at least the following information:

- date of the event (Year, Month, Day)
- time of the event (Hours, Minutes, Seconds)
- Timezone, those information belongs to

When logging, the applicable legal and operational regulations must be observed. The latter also include agreements that have been made with the company's social partners. Following these regulations logging of events is only allowed for a defined use case. Logging of events for doing a work control of employees is not allowed.

In addition - as for any data that is processed by a system - an appropriate protection requirement must also be taken into account and implemented for logging data; this applies to storage, transmission and access. In particular, if the logging data contains real data, the same protection requirements must be taken into account that is also used for the regular processing of this real data within the source system.

Typical event that reasonable should be logged in many cases are:

Event	**Event data to be logged**
Incorrect login attempts	• User account, • Number of failed attempts, • Source (IP address, client ID / client name) of remote access

System access from user accounts with administrator permissions	• User account, • Access timestamp, • Length of session, • Source (IP address) of remote access
Account administration	• Administrator account, • Administered user account, • Activity performed (configure, delete, enable and disable)
Change of group membership for accounts	• Administrator account, • Administered user account, • Activity performed (group added or removed)
Critical rise in system values such as disk space, CPU load over a longer period	• Value exceeded, • Value reached (Here suitable threshold values must be defined depending on the individual system.)

Logging of additional security-relevant events may be meaningful. This must be verified in individual cases and implemented accordingly where required.

Motivation: Logging security-relevant events is a basic requirement for detecting ongoing attacks as well as attacks that have already occurred. This is the only way in which suitable measures can be taken to maintain or restore system security. Logging data could be used as evidence to take legal steps against attackers.

For this requirement the following threats are relevant:
- Denial of executed activities
- Unnoticeable feasible attacks

For this requirement the following warranty objectives are relevant:

ID: 3.01-33/7.0

Req 28 Applicable retention and deletion periods must be observed for security-relevant logging data that is recorded locally.

From an IT security perspective, local storage of security-relevant logging data on a system is not mandatory. Since the local storage can be damaged in the event of system malfunctions or manipulated by a successful attacker, it can only be used to a limited extent for security-related or forensic analyses. Accordingly, it is relevant for IT security that logging data is forwarded to a separate log server.

Local storage can nevertheless take place; for example, if local storage is initially indispensable when generating the logging data due to technical processes or if there are justified operational interests in also keeping logging data available locally.

The following basic rules must be taken into account when storing logging data locally:

- Security-related logging data must be retained for a period of 90 days.
  (*This requirement only applies if no additional forwarding to a separate log server is implemented on the system and the logging data is therefore only recorded locally.*)
- After 90 days, stored logging data must be deleted immediately.

Deviances

Different retention periods and deletion periods may exist due to legal or regulatory requirements (especially in connection with personal data) or may be defined by contractual agreements. In these cases, the applicable periods must be agreed individually with a Project Security Manager (PSM) / Data Privacy Advisor (DPA) or are specified by them.

Motivation: Logging data is an immensely important IT security tool for preventing, detecting and clearing up system faults, security and data privacy incidents. On the other hand, the recording of logging data, like any other data processing, is also subject to legal and regulatory requirements. Accordingly, guidelines must be adhered to that reconcile the two.

Implementation example: Taking into account the current legal situation and applicable data privacy regulations, the following deletion periods for locally stored security-relevant logging data are implemented on an exemplary telecommunications system:

- Standard System Logs: Deletion after 90 days at the latest
- Logging of public IP addresses: Deletion (or anonymization) after 7 days at the latest
- Logging of the assignment of dynamic public IP addresses by the telecommunication solution: Deletion after 7 days at the latest
- Logging of non-billing-relevant call detail records: Deletion after 7 days at the latest
- Logging of the content of e-mail and SMS: Deletion after 24 hours at the latest
- Logging of the domain queries handled by the DNS server of the telecommunications solution: Deletion after 24 hours at the latest

For this requirement the following threats are relevant:

- Unauthorized access or tapping of data
- Denial of executed activities
- Unnoticeable feasible attacks

For this requirement the following warranty objectives are relevant:

ID: 3.01-34/7.0

Req 29	Security-relevant logging data must be forwarded to a separate log server immediately after it has been generated.

Logging data must be forwarded to a separate log server immediately after it has been generated. Standardized protocols such as Syslog, SNMPv3 should be preferred.

Motivation: If logging data is only stored locally, it can be manipulated by an attacker who succeeds in compromising the system in order to conceal his attack and any manipulation he has performed on the system. This is the reason why the forwarding must be done immediately after the event occurred.

For this requirement the following threats are relevant:

- Unauthorized modification of data
- Disruption of availability
- Denial of executed activities
- Unnoticeable feasible attacks

For this requirement the following warranty objectives are relevant:

ID: 3.01-35/7.0

Req 30	For security-relevant logging data that is forwarded to the separate log server, compliance with the applicable retention and deletion periods must be ensured.

The following basic rules must be taken into account:

- security-related logging data must be retained for a period of 90 days on the separate log server.
- after 90 days, stored logging data must be deleted immediately on the separate log server.

Deviances
Different retention periods and deletion periods may exist due to legal or regulatory requirements (especially in connection with personal data) or may be defined by contractual agreements. In these cases, the applicable periods must be agreed individually with a Project Security Manager (PSM) / Data Privacy Advisor (DSB) or are specified by them.

Log server under the responsibility of a third party
If the selected separate log server is not within the same operational responsibility as the source system of the loggin data, it must be ensured that the responsible operator of the log server is aware of the valid parameters for the logging data to be received and that they are adhered to in accordance with the regulations mentioned here.

Motivation: Logging data is an immensely important IT security tool for preventing, detecting and clearing up system faults, security and data privacy incidents. On the other hand, the recording of logging data, like any other data processing, is also subject to legal and regulatory requirements. Accordingly, guidelines must be adhered to that reconcile the two.

Implementation example: Taking into account the current legal situation and applicable data privacy regulations, the following deletion periods for forwarded security-relevant logging data from an exemplary telecommunications system are implemented on the separate log server:

- Standard System Logs: Deletion after 90 days at the latest
- Logging of public IP addresses: Deletion (or anonymization) after 7 days at the latest
- Logging of the assignment of dynamic public IP addresses by the telecommunication solution: Deletion after 7 days at the latest
- Logging of non-billing-relevant call detail records: Deletion after 7 days at the latest
- Logging of the content of e-mail and SMS: Deletion after 24 hours at the latest
- Logging of the domain queries handled by the DNS server of the telecommunications solution: Deletion after 24 hours at the latest

For this requirement the following threats are relevant:
- Unauthorized access or tapping of data
- Denial of executed activities
- Unnoticeable feasible attacks

For this requirement the following warranty objectives are relevant:

ID: 3.01-36/7.0

Req 31	The system must provide logging data that is required to detect the system-specific relevant forms of attack in a SIEM.

The forms of attack that are typically to be expected for the present system must be systematically analyzed and identified.
The MITRE Attack Matrix (https://attack.mitre.org) can be used as a structured guide during such an identification.

It must be ensured that the system generates appropriate logging data on events that are or may be related to these identified forms of attack and that can be used to detect an attack that is taking place.

The logging data must be sent to a SIEM immediately after the system event occurs.
SIEM (Security Information & Event Management) solutions collect event log data from various source systems, correlate it and evaluate it automatically in real time in order to detect anomalous activities such as ongoing attacks on IT/

NT systems and to be able to initiate alarms or countermeasures.
The immediate receipt of system events is therefore absolutely crucial for the SIEM to fulfill its protective functions.

Note:
The immediate need to connect a system to a SIEM is specifically regulated by the separate "Operation" security requirements catalogs.
If the present system does not fall under this need, the requirement may be answered as "not applicable".

Motivation: A SIEM as an automated detection system for attacks can only be effective if it continuously receives sufficient and, above all, system-specific relevant event messages from the infrastructures and systems to be monitored. General standard event messages may not be sufficient to achieve an adequate level of detection and only allow rudimentary attack detections.

Implementation example: An example system allows end users to log in using a username and password. One of the typical forms of attack for this system would be to try to discover and take over user accounts with weak or frequently used passwords by means of automated password testing (dictionary or brute force attack). The example system is configured to record every failed login event in system protocols ("logs"). By routing this logging data in parallel to a SIEM, the SIEM can detect in real time that an attack is obviously taking place, alert it and thus enable immediate countermeasures.

ID: 3.01-37/7.0

4.2. Auditing and monitoring

Req 32	Important database services and instances must be monitored continually for misuse scenarios.

The monitoring of user actions for misuse shall comply with national legislation currently in force (for details see the “Security Requirement on Misuse Detection”).

Motivation: There are many conceivable ways to misuse database systems. Users generate an unusually high data usage rate or operate at unusual times of day. Attackers utilize unusual and critical commands for database queries, as well as tools and malware to extend their rights. To detect misuse, database systems should be continually monitored for misuse scenarios, e.g. by means of database triggers and log monitoring.

For this requirement the following threats are relevant:
- Unauthorized access to the system
- Unauthorized access or tapping of data
- Unauthorized modification of data
- Unauthorized use of services or resources

For this requirement the following warranty objectives are relevant:

ID: 3.16-32/6.0
